↑ health connection

Apply this
model to

all sorts of population

↳ clinical, rehab,

chronic disease
(see how muscles
are functioning)

Δ slope of each exercise

end of
rotary to exam

calculate the

① value of y

② paper did

ΔV_{O2} - diff between the oxy Hb & deoxy Hb

recovery fit for the difference (deoxy Hb & oxy Hb)
and time.

* recovery kinetics, the faster the better (steeper) the slope the
better

calculated for each of the patients

$$y = (\text{end} - \text{delta}) \times e^{-at}$$

y = series of arterial occlusion in V_{O2}

end = values diff of Hb in the last second of exercise, where y is added to e
